Description

Field of the Invention

- 5 The invention relates to a method for the recovery of the valuable substances, particularly betaine and sucrose contained in beet molasses by simulated moving bed chromatography.

Background of the Invention

- 10 Betaine is a valuable compound which is used in animal fodders, as well as in pharmaceutical and cosmetic applications.

- Betaine occurs in the roots, seed and stems of a great variety of plants. Its concentration in sugar beet is relatively high, 1.0 to 1.5% on a dry solids basis. When sugar beet is processed for the recovery of sucrose, betaine concentrates in the molasses. Beet molasses usually contains from 3 to 8% of betaine calculated on a dry solids basis.

15 Betaine is an amphoteric compound having the formula:

It is known to recover betaine from beet molasses, rest molasses or vinasse by ion exchange, by crystallization as a hydrochloride, by extraction with an organic solvent, or by chromatography.

- 30 A chromatographic method for the recovery of betaine is described in U.S. Patent No. 4,359,430; this method is a process in which molasses which contains betaine, such as beet molasses, is introduced to the top of a column containing a polystyrene sulphonate cation exchange resin in alkali metal form at a flow rate of 0.5 to 2.0 m³/h/m². Elution with water is carried out for the recovery of betaine, sucrose and rest molasses from the downstream side of the resin bed.

- 35 Simulated or pseudo-moving bed chromatography, i.e., a multi-step separation process in which a solution containing two or more substances to be separated is circulated with respect to a stationary phase, has been used for the separation of two components, such as glucose/fructose from high-fructose syrups or sucrose/rest molasses from molasses.

- The first commercial simulated moving bed method was described in U.S. Patent No. 2,985,589. U.S. Patent No. 4,404,037 describes a simulated moving bed technique wherein carbon is used as an adsorbent for the recovery of sucrose from molasses. U.S. Patents 4,426,232 and 4,533,398 describe similar methods wherein zeolite is used as an adsorbent. U.S. Patent 3,997,357 describes a continuous method for the recovery of sucrose from molasses, and U.S. Patent Nos. 4,519,845, 4,332,623 and 4,405,455 methods for the separation of sucrose from molasses. U.S. Patent No. 4,461,649 describes a method for simulated counter-current separation of sugars. A summary of these separation methods is presented in e.g. Food Engineering (Anon) 1983 55 (5) p. 154, and Sugar y Azucar (1987) August, p. 27 and 29 (U. Bhawarda).

- 45 Commercial simulated moving bed methods are also described in U.S. Patent 3,732,982, U.S. Patent No. 4,412,866, and Chemical Engineering 1981 August/September p. 389 to 393 (P. Barker et al.). In EPO application No. 0279946, a simulated moving bed method is described for the separation of beet molasses into three or more fractions. However, the recovery of betaine is not disclosed and the performance of the method is low.

Beet molasses contains sucrose, betaine, salts, amino acids and other organic and inorganic components. It is highly desirable to recover betaine in the same cycle as sucrose. However, this has not been possible previously through the use of simulated moving bed methods.

- 55 In previous methods for the recovery of betaine from beet molasses using chromatographic methods, the separation capacity and/or the dry content of the separated fractions has been low.

It is therefore an object of the present invention to separate sucrose, betaine, and rest molasses using a chromatographic technique in which all three fractions are recovered during the same cycle.

It is another object of the present invention to recover a betaine-rich fraction by a single fractionation step with no post-fractionation required.

It is another object of the present invention to effect a high performance separation of betaine so that the separation capacity is high, the yield of the different components in the product fractions is high, and the consumption of eluent water is low.

BRIEF DESCRIPTION OF THE DRAWINGS

The following drawings are illustrative of embodiments of the invention and are not meant to limit the scope of the invention as encompassed by the claims.

FIGURE 1 is a schematic view of an apparatus having four chromatographic columns connected in series;

FIGURE 2 is a schematic view of an apparatus having eight chromatographic columns connected in series; and

FIGURE 3 is a graphical representation of the elution profile from column 8 of Example 1.

SUMMARY OF THE INVENTION

In accordance with the above-mentioned objects and others, the following invention provides an improved method for the recovery of betaine and sucrose by a chromatographic simulated moving bed technique comprising separating betaine by elution as a third fraction during the same cycle substantially simultaneously with sucrose and rest molasses.

More particularly, the present invention relates to a method for the recovery of betaine and sucrose from beet molasses during the same cycle of a chromatographic simulated moving bed system having at least three chromatographic columns connected in series and adapted for the flow of liquids in a single direction through the columns. The cycle comprises a molasses feeding step comprising feeding a molasses feed solution into one of the columns and substantially simultaneously feeding water into another of the columns, a water feeding step comprising feeding water into one of the columns, a circulation step comprising circulating the molasses feed solution and the water through the columns, and during said steps eluting a sucrose fraction from one of the columns, and a betaine fraction from one of the columns and a rest molasses fraction from one of the columns. Said steps are repeated 1 to 6 times during one cycle.

Preferably one or more, and most preferably two or three product fractions selected from the group consisting of sucrose, rest molasses and betaine are eluted from the columns during the molasses feeding step and the water feeding step. The betaine is preferably eluted during said water feeding step from the bottom of a column downstream (i.e., farther in the direction of flow of said system) from the column into which the water is fed.

In another embodiment, betaine is eluted as substantially separate fraction in addition to or instead of rest molasses during the water feeding step.

In another embodiment, the method further comprises a second circulation step wherein rest molasses is eluted between the first and second circulation steps. The column from which the rest molasses is eluted is positioned farther downstream from the column into which the water is fed.

In other embodiments, the sucrose may be eluted from the same column as betaine prior to said elution of said betaine, and the betaine and the rest molasses may be eluted one after the other from the same column.

Preferable cycles include from about 3 to 14 steps, the most preferable being from about 4 to about 8.

It is also preferable that there be provided from 3 to about 14 chromatographic columns connected in series, and more preferably from 4 to about 8 chromatographic columns connected in series. A chromatographic column may comprise one column or a plurality of short columns, each having feed distribution and eluent collecting means.

It is also preferable that the liquid flow rate in the columns is from about 0.5 to about 10 m³/h/m².

It is further preferred that an elevated temperature of from about 40 °C to about 85 °C is used during elution. It is also preferable that a strongly acidic cation exchange in monovalent form is used as the column filling material.

The eluent solution is preferably water because it is the most practical and economically advantageous. However, other eluents known to those skilled in the art may be used instead.

The present invention is also related to a method for the recovery of betaine and sucrose from beet molasses from a chromatographic simulated moving bed system having at least three chromatographic columns connected in series and adapted for the flow of liquids in a single direction through the columns,

sequentially comprising (1) feeding a molasses feed solution into one of the columns, substantially simultaneously feeding water into another column downstream from the column which is fed with the feed molasses solution, and substantially simultaneously eluting product fractions selected from the group consisting of a rest molasses fraction, a betaine fraction followed by a rest molasses fraction, a sucrose fraction, and a sucrose fraction followed by a betaine fraction; (2) circulating the molasses feed solution and the water in the direction of flow through the columns; (3) feeding water into one of the columns and eluting rest molasses, betaine, or both from a column downstream; (4) circulating the molasses feed solution and the water in the direction of flow through the columns; (5) repeating steps (2) and (3) about 1-6 times during one cycle; and (6) repeating step (1) about 1-2 times or more during one cycle.

The method may further comprise repeating the cycle continuously after equilibrium has been reached. By "equilibrium", it is meant that the composition of all fractions is constant and the sum of all fractions corresponds to the composition of the feed solution.

DETAILED DESCRIPTION

In the method according to the invention several chromatographic columns are used in series. The series may comprise 3 to about 14 columns. The columns are interconnected with pipelines so that the circulation through all the columns can be established with one pump only. In place of one pump, several pumps can be used; for instance, pumps can be provided between several or all columns. Preferably, the flow rate is 0.5 to 10 m³/h/m² of the cross-sectional area of the column. Referring to Figure 1, an apparatus comprising four chromatographic columns 1-4 connected in series is shown.

The columns are filled with a strongly acidic, gel-type cation exchange resin (e.g. "Zerolit 225" or "Finex C09") preferably in monovalent ion form, most preferably in sodium and/or potassium form.

Figure 2 shows another apparatus according to the present invention which is similar to that which is shown in Figure 1 but in which has eight columns 1-8 connected in series.

The columns are provided with feed lines 19, 20 and product lines 27-29 so that feed solution and eluent water can be fed into the columns and the product fraction collected from the column.

More particularly, a first container 17 is provided which contains diluted molasses fed to a preselected column. The molasses is fed to a preselected column via a molasses feed pump 22 into a molasses feed pipe 19. The apparatus is also provided with a second container 18 which contains water. The water is fed to a preselected column via a water feed pump 23 into a water feed pipe 20. The feed lines 19, 20 and product lines 27-29 as well as the pipelines interconnecting the columns 9-12 are provided with 30-60 valves so that the feeding and the collecting can be interrupted after a preselected amount of the solution has been fed or collected, respectively.

The product lines are provided with on-line instruments (not shown) so that the quality of the product can be monitored during operation. The on-line instruments include a density meter or the like; a refractive index meter, a conductivity meter, a meter for optical activity and a thermometer. The process control is carried out by a microprocessor or computer.

Before undergoing chromatographic separation, the feed solution (beet molasses) is diluted with water to a concentration of from about 40 to 60 percent by weight. The diluted feed solution is, after the addition of sodium carbonate to remove calcium as calcium carbonate, filtered using diatomaceous earth as a filter aid. Before feeding into the separation columns 1-4, the molasses solution is heated by heat exchanger 24 to a temperature ranging from about 50 ° to about 85 ° C.

Elution is carried out with water which is provided via water container 18, water feed pipe 20, and water feed pump 23. The water is preferably heated in heat exchanger 26 to a temperature of from about 50 ° to about 85 ° C before the elution step is carried out.

During the separation, the feed solution batch is circulated through the column series by means of the pump 21. A new portion of feed solution is added to the column series between partly separated rest molasses and sucrose fractions to the top of a preselected column.

For example, when the feed solution is fed into the first column, betaine and rest molasses fractions may be collected from the bottom of the second column. The third column is simultaneously fed with water, and a sucrose fraction can be collected from the fourth column.

It is also possible to elute the sucrose and betaine fractions one after another from the same column by feeding eluent water to the top of a preceding column in the column series. As appears from Figure 3, sucrose and betaine fractions thereby partly overlap; however, the fractions obtained have sufficient purity.

After the feeding of the feed solution and the eluent water into the columns and the collecting of the product fractions, the circulation of the solutions contained in the columns is started. The circulation of the solutions is continued throughout the entire series of columns until a new batch of feed solution and/or

eluent water can be fed again in the same preselected columns as previously used.

If desired, the circulation can be interrupted, and water can be fed into the column downstream from the preceding water feeding point for collecting a rest molasses and/or betaine fraction from a column positioned downstream in the column series.

5 The circulation can be continued until the following feed solution batch or eluent water batch is fed into columns positioned downstream in the column series than during the previous cycle. This improves the efficiency of the separation.

The manner in which it is determined which column is to be eluted in order to obtain betaine, sucrose or rest molasses in accordance with present invention is well known in the art. For example, the elution of
10 sucrose may be determined by on-line optical activity measurement. The elution of ionic non-sugars may be determined by on-line conductivity measurement. The elution of betaine may be determined by the analysis of collected samples. The elution of rest molasses is begun when the density and conductivity measurements begin to increase. These measurements are used to determine the optimum volumes of fractions. In addition, the total dry substance content of a fraction may be determined by an on-line density
15 measurement.

The sucrose content of the sucrose fraction obtained by the method of the present invention may vary from about 80 to about 95% on a dry solids basis, and the betaine content of the betaine fraction from about 25 to about 80% on a dry solids basis. The sucrose content of the rest molasses fraction may vary from about 15 to about 30% on a dry solids basis. These values, however, do not represent the actual
20 limits of the performance of the new methods; they are mere examples of a normal operation when using beet molasses containing about 60% of sucrose and about 4.5 to 5.5% of betaine on a dry solids basis.

The dry substance content of the sucrose fraction may vary from 25 to about 35% by weight, and the dry substance content of the betaine fraction and the rest molasses fraction from about 4 to about 10% by weight. These, too, are mere examples of the performances of the new method. The dry content of beet
25 molasses is about 80%.

Betaine may then be recovered from the betaine fraction by any method known in the art. Preferred processes which may be used to recover betaine or pharmaceutical grade betaine monohydrate are set forth in U.S. Patent No. 4,359,430.

30 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

In the following examples the present invention will be illustrated in more detail by describing the separation of betaine, sucrose and rest molasses from beet molasses substantially simultaneously during the same cycle using a chromatographic simulated moving bed technique. These examples should not be
35 considered to restrict the scope of the invention; instead, they are mere examples of the use of the chromatographic simulated moving bed technique for the recovery of betaine from beet molasses as a third fraction substantially simultaneously with sucrose and rest molasses during the same cycle.

Example 1

40 A pilot scale chromatographic equipment was used. A flow sheet is provided in Figure 2. It comprised eight columns, a feed pump, a circulation pump, an eluent water pump, flow control and pressure control devices, and valves for inlets and outlets of different process streams.

The columns, each of which had a diameter of 200 mm, were filled with a strongly acidic cation
45 exchange resin ("Finex C09", produced by Finnish Sugar Co. Ltd.). The resin had a polystyrene divinylbenzene matrix and it contained sulphonic acid groups. The resin bed height was 1250 mm in all columns. The average particle size was about 0.36 mm. The resin was initially regenerated into sodium form. During the run it was gradually equilibrated with the cations contained in the feed molasses. After equilibrium has been achieved, the process can be continued as such for weeks without major changes. The temperature of the
50 solutions introduced into the columns was about 70 °C, and the flow rate was 120 liters per hour (l/h).

The feed solution was beet molasses from which calcium had been precipitated by adding sodium carbonate (pH 9). The calcium carbonate precipitate was filtered off.

The separation of sucrose and betaine was carried out by a 5-step sequence where every column had its specific function. The columns were connected in series and the flow direction was always from column
55 no. 1 to column no. 2 etc., and from column no. 8 back to column no. 1, as follows:

Step 1: Molasses was fed into column 1 and rest molasses was eluted from column 6. At the same time water was fed into column 7, and sucrose and betaine, in that order, were eluted from column 8 (see Figure 3).

- Step 2: Water was fed into column 7 and rest molasses was eluted from column 6.
 Step 3: Circulation of the solution in all the columns by the circulation pump.
 Step 4: Water was fed into column 3 and rest molasses was eluted from column 2.
 Step 5: Circulation in all columns.

When the sequence had come to its end, the process control program went on by returning to step 1. By repeating these sequences 5 to 7 times the system was equilibrated and product fractions with constant compositions were eluted and analyzed (see Tables 1 and 2).

The separation was controlled by a microprocessor determining accurately specified volumes of the feed, the circulation and the product fractions.

Table 1 shows the feed, circulation and product fraction volumes. Table 2 shows the compositions of the feed and of the product fractions by weight on a dry solids basis. Figure 3 is a graphical representation of the elution profile from column no. 1, showing the concentration of salts, oligosaccharides, sucrose and betaine as a function of time.

Table 1

Sucrose fraction	0.295	86.8	3.3	9.9

Example 2

The equipment, the resin and the conditions were the same as in Example 1, except for the flow rate, which was 150 l/h.

The process control was carried out by a 2x7-step sequence. The steps 1 to 7 comprise feeding one batch of molasses and three water elution steps. The operations in steps 8 to 14 were identical to those in steps 1 to 7, but were performed four columns farther downstream (in the direction of flow of the column series):

- Step 1: Molasses solution was fed into column 7 and rest molasses was eluted from column 4. At the same time water was fed into column 5 and sucrose eluted from column 6.
 Step 2: Circulation in all columns.
 Step 3: Water was fed into column 1 and rest molasses was eluted from column 8.
 Step 4: Circulation in all columns.
 Step 5: Water was fed into column 5 and at the same time betaine and rest molasses, in that order, were eluted from column 4.
 Step 6: Circulation in all columns.
 Step 7: Water was fed into column 1 and betaine was eluted from column 8.
 Step 8: Molasses solution was fed into column 3 and rest molasses was eluted from column 8, and

- at the same time water was fed into column 1 and sucrose was eluted from column 2.
- Step 9: Circulation in all columns.
- Step 10: Water was fed into column 5 and rest molasses was eluted from column 4.
- Step 11: Circulation in all columns.
- 5 Step 12: Water was fed into column 1 and at the same time betaine and rest molasses, in that order, were eluted from column 8.
- Step 13: Circulation in all columns.
- Step 14: Water was fed into column 5 and betaine was eluted from column 4.
- Table 3 shows the feed, circulation and product fraction volumes, and Table 4 the compositions of the
 10 feed and the product fractions.

Sucrose fraction	0.281	92.5	0.9	6.6

40 Example 3

The equipment, the resin and the conditions were the same as in Example 2. The process was controlled, as in Example 2, by a 2x7-step sequence. The operations in steps 8 and 14 were identical to those in steps 1 to 7, but they were performed four columns downstream. The main difference was that the
 45 betaine fraction was recovered separately from one predetermined column.

- Step 1: Molasses was fed into column 1 and rest molasses was eluted from column 4. At the same time water was fed into column 5 and sucrose eluted from column 6.
- Step 2: Circulation in all columns.
- Step 3: Water was fed into column 1 and rest molasses was eluted from column 8.
- 50 Step 4: Circulation in all columns.
- Step 5: Water was fed into column 5 and rest molasses was eluted from column 4.
- Step 6: Circulation in all columns.
- Step 7: Water was fed into column 1 and betaine was eluted from column 8.
- Step 8: Molasses was fed into column 5 and rest molasses was eluted from column 8. At the same
 55 time, water was fed into column 1 and sucrose eluted from column 2.
- Step 9: Circulation in all columns.
- Step 10: Water was fed into column 5 and rest molasses was eluted from column 4.
- Step 11: Circulation in all columns.

Step 12: Water was fed into column 1 and rest molasses was eluted from column 8.

Step 13: Circulation in all columns.

Step 14: Water was fed into column 5 and betaine was eluted from column 4.

The fraction volumes appear from Table 5, and the compositions of the feed and product fractions from

5 Table 6.

Example 4

The equipment, the resin and the conditions were the same as in Examples 1 to 3, except for the number of the columns, which was 4, and the flow rate, which was 120 l/h (the feed, the circulation, and the elution of rest molasses) and 280 l/h (the elution of sucrose and betaine). The height of the resin bed was 2500 mm.

The process was controlled by an 8-step sequence.

Step 1: Molasses was fed into column 1 and rest molasses was eluted from column 3. At the same time water was fed into column 4, and sucrose and betaine, in that order, were eluted from the bottom of the same column.

Step 2: Circulation in all columns.

Step 3: Water was fed into column 1 and rest molasses was eluted from column 4.

Step 4: Circulation in all columns.

Step 5: Water fed into column 2 and rest molasses was eluted from column 1.

Step 6: Circulation in all columns.

Step 7: Water fed into column 2 and rest molasses was eluted from column 2.

Step 8: Circulation in all columns.

The feed, circulation and product fraction volumes appear from Table 7 and the compositions of the feed and the product fractions from Table 8.

Many other variations of the present invention would be obvious to those skilled in the art, and are contemplated to be within the scope of the appended claims.

Claims

1. A method for the recovery of betaine and sucrose from beet molasses by using a chromatographic simulated moving bed system having at least three chromatographic columns connected in series and adapted for the flow of liquids in a single direction through the columns, **characterized** in that said betaine and sucrose are separated during same cycle, said cycle comprising
 - a molasses feeding step comprising feeding a molasses feed solution into one of said columns and substantially simultaneously feeding eluent, preferably water, into another of said columns,
 - an eluent, preferably water feeding step comprising feeding eluent, preferably water, into one of said columns,
 - a circulation step comprising circulating said molasses feed solution and said eluent, preferably water through said columns, and
 - eluting product fractions during said steps selected from the group consisting of a rest molasses fraction, a betaine fraction followed by a rest molasses fraction, a sucrose fraction, and a sucrose fraction followed by a betaine fraction, and
 - repeating said steps 1 to 6 times during one cycle.
2. The method of claim 1, further comprising eluting a sucrose and a betaine fraction sequentially from one of said columns.
3. The method of claim 1 or 2, wherein said molasses feeding step and said water feeding step further comprise eluting two or three product fractions selected from the group consisting of sucrose, rest molasses and betaine from one of said columns.
4. The method of claim 3, wherein said betaine is eluted during said water feeding step from a column downstream from the column into which the water is fed.
5. The method of claim 3, further comprising eluting said rest molasses as a substantially separate fraction in addition to said betaine during said water feeding step.

6. The method of claim 1, further comprising eluting said betaine and said rest molasses one after the other from the same column.
7. The method of claim 1, further comprising providing from 3 to about 14, preferably from 4 to about 8, chromatographic columns connected in series.
8. The method of claim 1, wherein a strongly acidic cation exchange resin is used as an adsorbent in said chromatographic columns.
9. The method of claim 8, wherein said strongly acidic cation exchange resin is in monovalent form, preferably in sodium or potassium form, or a mixture of said forms.
10. The method of claim 1, wherein the liquid flow rate in said columns is from about 0.5 to about 10 m³/h/m².
11. The method of claim 1, wherein the temperature of said circulating feed solution and water is from about 40° to about 85°C.
12. A method for the recovery of betaine and sucrose from beet molasses from a chromatographic simulated moving bed system having at least three chromatographic columns connected in series and adapted for the flow of liquids in a single direction through the columns, sequentially comprising
 - (1) feeding a molasses feed solution into one of said columns and eluting a rest molasses fraction from a column downstream from said column which is fed with said molasses feed solution;
 - (2) feeding water into one of said columns downstream from said column which is fed with said feed molasses solution at substantially the same time as said feeding of said molasses feed solution, and eluting product fractions comprising a sucrose fraction followed by a betaine fraction from a column downstream from said column which is fed with water;
 - (3) circulating said molasses feed solution and the water in said direction of flow through said columns;
 - (4) feeding water into one of said columns and eluting rest molasses from a column downstream from said column which is fed with water;
 - (5) circulating said molasses feed solution and the water in said direction of flow through said columns;
 - (6) feeding water into one of said columns and eluting rest molasses from a column downstream from said column which is fed with water; and
 - (7) circulating said molasses feed solution and the water in said direction of flow through said columns.
13. The method of claim 12, further comprising repeating steps 1-7 starting with feeding a molasses feed solution into a column downstream from said column into which said molasses feed solution was fed during the previous cycle.
14. A method for the recovery of betaine and sucrose from beet molasses using a chromatographic simulated moving bed system having at least three chromatographic columns connected in series and adapted for the flow of liquids in a single direction through the columns, sequentially comprising
 - (1) feeding a molasses feed solution into one of said columns and eluting a rest molasses fraction from a column downstream from said column which is fed with said molasses feed solution;
 - (2) feeding water into one of said columns downstream from said column which is fed with said feed molasses solution at substantially the same time as said feeding of said molasses feed solution, and eluting a product fraction selected from the group consisting of sucrose, betaine and a sucrose fraction followed by a betaine fraction from a column downstream from said column which is fed with water;
 - (3) circulating said molasses feed solution and the water in said direction of flow through said columns;
 - (4) feeding water into one of said columns and eluting rest molasses from a column downstream from said column which is fed with water;
 - (5) circulating said molasses feed solution and the water in said direction of flow through said columns;

- (6) feeding water into one of said columns and eluting betaine from a column downstream from said column which is fed with water; and
 (7) circulating said molasses feed solution and the water in said direction of flow through said columns.

- 5 15. The method of claim 1, 2, 12 or 14 further comprising repeating said cycle after equilibrium has been reached.
- 10 16. The method of claim 15, further comprising repeating steps 1-7 starting with feeding a molasses feed solution into a column downstream from said column into which said molasses feed solution was fed during the previous cycle.

Patentansprüche

- 15 1. Methode zur Gewinnung von Betain und Saccharose aus Rübenmelasse durch Einsatz eines chromatographischen Systems mit simuliertem Bewegtbett mit mindestens drei chromatographischen, hintereinandergeschalteten Säulen, in denen Flüssigkeiten in einer Richtung durch die Säulen fließen können, **dadurch gekennzeichnet**, daß das genannte Betain und die genannte Saccharose in einem Zyklus getrennt werden, wobei der genannte Zyklus folgendes umfaßt:
- 20 einen Melasse-Einspeiseschritt, der das Einspeisen einer Melasse-Einsatzlösung in eine der genannten Säulen und im wesentlichen das gleichzeitige Einspeisen eines Elutions-Stoffes, vorzugsweise Wasser, in eine andere der genannten Säulen umfaßt,
- einen Elutionsstoff-Einspeiseschritt, wobei der Elutionsstoff vorzugsweise Wasser ist, der das Einspeisen eines Elutionsstoffes, vorzugsweise Wasser, in eine der genannten Säulen umfaßt,
- 25 einen Zirkulationsschritt, der das Zirkulieren der genannten Melasse-Einsatzlösung und des genannten Elutionsstoffes, vorzugsweise Wasser, durch die genannten Säulen umfaßt, und
- Eluieren von Produktfraktionen während der genannten Schritte, die aus der Gruppe, zu der eine Restmelasse-Fraktion, eine von einer Restmelasse-Fraktion gefolgte Betain-Fraktion, eine Saccharose-Fraktion und eine von einer Betain-Fraktion gefolgte Saccharose-Fraktion gehören, ausgewählt werden;
- 30 und
- 1- bis 6-maliges Wiederholen der genannten Schritte im Verlauf eines Zyklus.
2. Methode nach Anspruch 1, weiter umfassend das nacheinander erfolgende Eluieren einer Saccharose- und einer Betain-Fraktion aus einer der genannten Säulen.
- 35 3. Methode nach Anspruch 1 oder 2, bei der der genannte Melasse-Einspeiseschritt und der genannte Wasser-Einspeiseschritt weiter das Eluieren von zwei oder drei Produktfraktionen umfassen, die aus der Gruppe, zu der Saccharose, Restmelasse und Betain gehören, ausgewählt werden, aus einer der genannten Säulen.
- 40 4. Methode nach Anspruch 3, bei der das genannte Betain während des genannten Wassereinspeiseschritts aus einer Säule eluiert wird, die hinter der Säule liegt, in die das Wasser eingespeist wird.
5. Methode nach Anspruch 3, weiter die Elution der genannten Restmelasse als eine im wesentlichen getrennte Fraktion zusätzlich zu dem genannten Betain während des genannten Wassereinspeiseschritts umfassend.
- 45 6. Methode nach Anspruch 1, weiter die nacheinander erfolgende Elution des genannten Betains und der genannten Restmelasse aus derselben Säule umfassend.
- 50 7. Methode nach Anspruch 1, weiter die Bereitstellung von 3 bis etwa 14, vorzugsweise 4 bis etwa 8, chromatographische, hintereinandergeschaltete Säulen umfassend.
8. Methode nach Anspruch 1, bei der ein stark saures Kationenaustauschharz in den genannten chromatographischen Säulen als Adsorptionsmittel eingesetzt wird.
- 55 9. Methode nach Anspruch 8, bei der das genannte stark saure Kationenaustauschharz in monovalenter Form vorliegt, vorzugsweise in Form von Natrium oder Kalium, oder als Mischung der genannten

Formen.

10. Methode nach Anspruch 1, bei der die Strömungsmenge der Flüssigkeit in den genannten Säulen zwischen etwa 0,5 bis etwa 10 m³/h/m² liegt.

11. Methode nach Anspruch 1, bei der die Temperatur der genannten umlaufenden Einsatzlösung und des Wassers zwischen 40 bis etwa 85 °C liegt.

12. Methode zur Gewinnung von Betain und Saccharose aus Rübenmelasse aus einem chromatographischen System mit simuliertem Bewegtbett, in der mindestens drei chromatographische Säulen hintereinandergeschaltet sind, in denen die Flüssigkeiten in einer Richtung durch die Säulen fließen, die nacheinander die folgenden Schritte umfaßt:

(1) Einspeisen einer Melasse-Einsatzlösung in eine der genannten Säulen und Eluieren einer Restmelasse-Fraktion aus einer Säule, die hinter der genannten Säule, in die die genannte Melasse-Einsatzlösung eingespeist wird, angeordnet ist;

(2) Einspeisen von Wasser in eine der genannten Säulen hinter der genannten Säule, in die die genannte Melasse-Einsatzlösung eingespeist wird, im wesentlichen gleichzeitig mit dem genannten Einspeisen der genannten Melasse-Einsatzlösung, und Eluieren von Produktfraktionen, eine von einer Betain-Fraktion gefolgte Saccharose-Fraktion umfassend, aus einer Säule die hinter der genannten Säule, in die das Wasser eingespeist wird, angeordnet ist;

(3) Zirkulieren der genannten Melasse-Einsatzlösung und des Wassers in der genannten Strömungsrichtung durch die genannten Säulen;

(4) Einspeisen von Wasser in eine der genannten Säulen und Eluieren von Restmelasse aus einer Säule, die hinter der genannten Wassereinspeisesäule angeordnet ist;

(5) Zirkulieren der genannten Melasse-Einsatzlösung und des Wassers in der genannten Strömungsrichtung durch die genannten Säulen;

(6) Einspeisen von Wasser in eine der genannten Säulen und Eluieren von Restmelasse aus einer Säule, die hinter der genannten Wassereinspeisesäule angeordnet ist; und

(7) Zirkulieren der genannten Melasse-Einsatzlösung und des Wassers in der genannten Strömungsrichtung durch die genannten Säulen.

13. Methode nach Anspruch 12, weiter das Wiederholen der Schritte 1-7 umfassend, beginnend mit dem Einspeisen einer Melasse-Einsatzlösung in eine Säule, die hinter der genannten Säule, in die die genannte Melasse-Einsatzlösung während des vorherigen Zyklus eingespeist wurde, angeordnet ist.

14. Methode zur Gewinnung von Betain und Saccharose aus Rübenmelasse unter Einsatz eines chromatographischen Systems mit simuliertem Bewegtbett mit mindestens drei chromatographischen, hintereinandergeschalteten Säulen, in denen die Flüssigkeiten in einer Richtung durch die Säulen fließen können, nacheinander folgende Schritte umfassend:

(1) Einspeisen einer Melasse-Einsatzlösung in eine der genannten Säulen und Eluieren einer Restmelasse-Fraktion aus einer Säule, die hinter der genannten Säule, in die die genannte Melasse-Einsatzlösung eingespeist wird, angeordnet ist;

(2) Einspeisen von Wasser in eine der genannten Säulen hinter der genannten Säule, in die die genannte Melasse-Einsatzlösung eingespeist wird, im wesentlichen gleichzeitig mit der Einspeisung der genannten Melasse-Einsatzlösung, und Eluieren einer Produktfraktion aus der Gruppe, zu der Saccharose, Betain und eine von einer Betain-Fraktion gefolgte Saccharose-Fraktion gehören, aus einer Säule hinter der genannten Wassereinspeisesäule;

(3) Zirkulieren der genannten Melasse-Einsatzlösung und des Wassers in der genannten Strömungsrichtung durch die genannten Säulen;

(4) Einspeisen von Wasser in eine der genannten Säulen und Eluieren von Restmelasse aus einer Säule hinter der genannten Wassereinspeisesäule;

(5) Zirkulieren der genannten Melasse-Einsatzlösung und des Wassers in der genannten Strömungsrichtung durch die genannten Säulen;

(6) Einspeisen von Wasser in eine der genannten Säulen und Eluieren von Betain aus einer Säule hinter der genannten Wassereinspeisesäule; und

(7) Zirkulieren der genannten Melasse-Einsatzlösung und des Wassers in der genannten Strömungsrichtung durch die genannten Säulen.

15. Methode nach Anspruch 1, 2, 12 oder 14, weiter umfassend das Wiederholen des genannten Zyklus, nachdem ein Gleichgewicht erreicht wurde.
16. Methode nach Anspruch 15, weiter umfassend das Wiederholen der Schritte 1-7, beginnend mit dem Einspeisen einer Melasse-Einsatzlösung in eine Säule, die hinter der genannten Säule, in die die genannte Melasse-Einsatzlösung während des vorherigen Zyklus eingespeist wurde, angeordnet ist.

Revendications

- 10 1. Procédé de récupération de bétanine et de saccharose provenant d'une mélasse de betterave par l'utilisation d'un système chromatographique simulé en lit mobile ayant au moins trois colonnes chromatographiques placées en série et adaptées pour l'écoulement des liquides dans une direction unique dans les colonnes, caractérisé en ce que la bétanine et le saccharose sont séparés lors du même cycle, ledit cycle comprenant
- 15 une étape d'alimentation en mélasse comprenant l'introduction d'une solution d'alimentation de mélasse dans l'une desdites colonnes et l'introduction d'une manière sensiblement simultanée d'un éluant, de préférence l'eau, dans une autre desdites colonnes,
- une étape d'alimentation en éluant, de préférence l'eau, comprenant l'introduction de l'éluant, de préférence l'eau, dans l'une desdites colonnes,
- 20 une étape de circulation comprenant la circulation de ladite solution d'alimentation de mélasse et dudit éluant, de préférence l'eau, dans lesdites colonnes et
- l'élution des fractions de produits lors desdites étapes choisies dans le groupe constitué d'une fraction de mélasse restante, d'une fraction de bétanine suivie d'une fraction de mélasse restante, d'une fraction de saccharose et d'une fraction de saccharose suivie d'une fraction de bétanine et ainsi que
- 25 la répétition desdites étapes de 1 à 6 fois pendant un cycle.
2. Procédé selon la revendication 1, comprenant de plus l'élution d'une fraction de saccharose et d'une fraction de bétanine consécutivement à partir de l'une desdites colonnes.
- 30 3. Procédé selon la revendication 1 ou 2, dans lequel ladite étape d'alimentation en mélasse et ladite étape d'alimentation en eau comprennent de plus l'élution de deux ou trois fractions de produits choisies dans le groupe constitué du saccharose, de la mélasse restante et de la bétanine à partir de l'une desdites colonnes.
- 35 4. Procédé selon la revendication 3, dans lequel ladite bétanine est éluee lors de ladite étape d'alimentation en eau à partir d'une colonne en aval par rapport à la colonne dans laquelle on introduit l'eau.
5. Procédé selon la revendication 3, comprenant de plus l'élution de ladite mélasse restante en tant que fraction sensiblement séparée, outre ladite bétanine, lors de ladite étape d'alimentation en eau.
- 40 6. Procédé selon la revendication 1, comprenant de plus l'élution de ladite bétanine et de ladite mélasse restante l'une après l'autre à partir de la même colonne.
7. Procédé selon la revendication 1, comprenant de plus l'apport de 3 à environ 14, de préférence de 4 à environ 8 colonnes chromatographiques placées en série.
- 45 8. Procédé selon la revendication 1, dans lequel on utilise une résine échangeuse de cations fortement acides comme adsorbant dans lesdites colonnes chromatographiques.
- 50 9. Procédé selon la revendication 8, dans lequel ladite résine échangeuse de cations fortement acides se trouve sous une forme monovalente, de préférence sous une forme sodium ou potassium, ou sous un mélange desdites formes.
10. Procédé selon la revendication 1, dans lequel le débit de liquide dans lesdites colonnes est compris entre environ 0,5 et environ 10 m³/h/m².
- 55 11. Procédé selon la revendication 1, dans lequel la température de ladite solution d'alimentation et de ladite eau qui circulent est comprise entre environ 40 °C et environ 85 °C.

12. Procédé de récupération de bétaine et de saccharose provenant d'une mélasse de betterave à partir d'un système chromatographique simulé en lit mobile ayant au moins trois colonnes chromatographiques placées en série et adaptées pour l'écoulement des liquides dans une direction unique dans les colonnes, comprenant consécutivement

- 5 (1) l'introduction d'une solution d'alimentation de mélasse dans l'une desdites colonnes et l'élution d'une fraction de mélasse restante à partir d'une colonne en aval par rapport à ladite colonne qui est alimentée avec ladite solution d'alimentation de mélasse,
- (2) l'introduction d'eau dans l'une desdites colonnes en aval par rapport à ladite colonne qui est alimentée avec ladite solution d'alimentation de mélasse pratiquement en même temps que ladite
- 10 introduction de ladite solution d'alimentation de mélasse, et l'élution des fractions de produits comprenant une fraction de saccharose suivie d'une fraction de bétaine à partir d'une colonne en aval par rapport à ladite colonne qui est alimentée avec l'eau,
- (3) la circulation de ladite solution d'alimentation de mélasse et de l'eau dans ladite direction d'écoulement dans lesdites colonnes,
- 15 (4) l'introduction d'eau dans l'une desdites colonnes et l'élution de la mélasse restante à partir d'une colonne en aval par rapport à ladite colonne qui est alimentée avec l'eau,
- (5) la circulation de ladite solution d'alimentation de mélasse et de l'eau dans ladite direction d'écoulement dans lesdites colonnes,
- (6) l'introduction d'eau dans l'une desdites colonnes et l'élution de la mélasse restante à partir d'une
- 20 colonne en aval par rapport à ladite colonne qui est alimentée avec l'eau et
- (7) la circulation de ladite solution d'alimentation de mélasse et de l'eau dans ladite direction d'écoulement dans lesdites colonnes.

13. Procédé selon la revendication 12, comprenant de plus la répétition des étapes 1 à 7 en commençant
- 25 par l'introduction d'une solution d'alimentation de mélasse dans une colonne en aval par rapport à ladite colonne dans laquelle on a introduit ladite solution d'alimentation de mélasse lors du cycle précédent.

14. Procédé de récupération de bétaine et de saccharose provenant d'une mélasse de betterave en
- 30 utilisant un système chromatographique simulé en lit mobile ayant au moins trois colonnes chromatographiques placées en série et adaptées pour l'écoulement des liquides dans une direction unique dans les colonnes, comprenant consécutivement

- 35 (1) l'introduction d'une solution d'alimentation de mélasse dans l'une desdites colonnes et l'élution d'une fraction de mélasse restante à partir d'une colonne en aval par rapport à ladite colonne qui est alimentée avec ladite solution d'alimentation de mélasse,
- (2) l'introduction d'eau dans l'une desdites colonnes en aval par rapport à ladite colonne qui est alimentée avec ladite solution d'alimentation de mélasse pratiquement en même temps que ladite
- 40 introduction de ladite solution d'alimentation de mélasse, et l'élution d'une fraction de produit choisie dans le groupe constitué de saccharose, de bétaine et d'une fraction de saccharose suivie d'une fraction de bétaine à partir d'une colonne en aval par rapport à ladite colonne qui est alimentée avec l'eau,
- (3) la circulation de ladite solution d'alimentation de mélasse et de l'eau dans ladite direction d'écoulement dans lesdites colonnes,
- (4) l'introduction d'eau dans l'une desdites colonnes et l'élution de la mélasse restante à partir d'une
- 45 colonne en aval par rapport à ladite colonne qui est alimentée avec l'eau,
- (5) la circulation de ladite solution d'alimentation de mélasse et de l'eau dans ladite direction d'écoulement dans lesdites colonnes,
- (6) l'introduction d'eau dans l'une desdites colonnes et l'élution de la bétaine à partir d'une colonne en aval par rapport à ladite colonne qui est alimentée avec l'eau et
- 50 (7) la circulation de ladite solution d'alimentation de mélasse et de l'eau dans ladite direction d'écoulement dans lesdites colonnes.

15. Procédé selon la revendication 1, 2, 12 ou 14, comprenant de plus la répétition dudit cycle après avoir atteint l'équilibre.

- 55 16. Procédé selon la revendication 15, comprenant de plus la répétition des étapes 1 à 7 en commençant par l'introduction d'une solution d'alimentation de mélasse dans une colonne en aval par rapport à ladite colonne dans laquelle on a introduit ladite solution d'alimentation de mélasse pendant le cycle

précédent.
